

Lecture 12

Multiple Linear Regression

DSC 40A, Fall 2024

Agenda

- Recap: regression and linear algebra
- Multiple linear regression.
- Interpreting parameters.

Recap: Regression and linear algebra

Regression and linear algebra (Solution 1)

- Define the design matrix $X \in \mathbb{R}^{n \times 2}$, observation vector $\vec{y} \in \mathbb{R}^n$, and parameter vector $\vec{w} \in \mathbb{R}^2$ as:

$$X = \begin{bmatrix} 1 & x_1 \\ 1 & x_2 \\ \vdots & \vdots \\ 1 & x_n \end{bmatrix} \quad \vec{y} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} \quad \vec{w} = \begin{bmatrix} w_0 \\ w_1 \end{bmatrix}$$

- How do we make the hypothesis vector, $\vec{h} = X\vec{w}$, as close to \vec{y} as possible? Use the parameter vector \vec{w}^* :

$$\vec{w}^* = (X^T X)^{-1} X^T \vec{y}$$

- Solution: We chose \vec{w}^* so that $\vec{h}^* = X\vec{w}^*$ is the projection of \vec{y} onto the span of the columns of the design matrix, X and minimized the length of the projection error $\|\vec{e}\| = \|\vec{y} - X\vec{w}\|$.

Regression and linear algebra (Solution 2)

- Define the design matrix $X \in \mathbb{R}^{n \times 2}$, observation vector $\vec{y} \in \mathbb{R}^n$, and parameter vector $\vec{w} \in \mathbb{R}^2$ as:

$$X = \begin{bmatrix} 1 & x_1 \\ 1 & x_2 \\ \vdots & \vdots \\ 1 & x_n \end{bmatrix} \quad \vec{y} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} \quad \vec{w} = \begin{bmatrix} w_0 \\ w_1 \end{bmatrix}$$

- How do we minimize the mean squared error $R_{\text{sq}}(\vec{w}) = \frac{1}{n} \|\vec{y} - X\vec{w}\|^2$? Using calculus the optimal parameter vector \vec{w}^* is:

$$\vec{w}^* = (X^T X)^{-1} X^T \vec{y}$$

- Solution: we computed the gradient of $R_{\text{sq}}(\vec{w})$, set it to zero and solved for \vec{w} .

Multiple linear regression

	departure_hour	day_of_month	minutes
0	10.816667	15	68.0
1	7.750000	16	94.0
2	8.450000	22	63.0
3	7.133333	23	100.0
4	9.150000	30	69.0
...

So far, we've fit **simple** linear regression models, which use only **one** feature (`'departure_hour'`) for making predictions.

Incorporating multiple features

- In the context of the commute times dataset, the simple linear regression model we fit was of the form:

$$\begin{aligned}\text{pred. commute} &= H(\text{departure hour}) \\ &= w_0 + w_1 \cdot \text{departure hour}\end{aligned}$$

- Now, we'll try and fit a multiple linear regression model of the form:

$$\begin{aligned}\text{pred. commute} &= H(\text{departure hour}) \\ &= w_0 + w_1 \cdot \text{departure hour} + w_2 \cdot \text{day of month}\end{aligned}$$

- Linear regression with **multiple** features is called **multiple linear regression**.
- How do we find w_0^* , w_1^* , and w_2^* ?

Geometric interpretation

- The hypothesis function:

$$H(\text{departure hour}) = w_0 + w_1 \cdot \text{departure hour}$$

looks like a **line** in 2D.

- Questions:

- How many dimensions do we need to graph the hypothesis function:

$$H(\text{departure hour}) = w_0 + w_1 \cdot \text{departure hour} + w_2 \cdot \text{day of month}$$

- What is the shape of the hypothesis function?

Commute Time vs. Departure Hour and Day of Month

Our new hypothesis function is a **plane** in 3D!

Our goal is to find the **plane** of best fit that pierces through the cloud of points.

The setup

- Suppose we have the following dataset.

	departure_hour	day_of_month	minutes
row			
1	8.45	22	63.0
2	8.90	28	89.0
3	8.72	18	89.0

- We can represent each day with a **feature vector**, \vec{x} :

The hypothesis vector

- When our hypothesis function is of the form:

$$H(\text{departure hour}) = w_0 + w_1 \cdot \text{departure hour} + w_2 \cdot \text{day of month}$$

the hypothesis vector $\vec{h} \in \mathbb{R}^n$ can be written as:

$$\vec{h} = \begin{bmatrix} H(\text{departure hour}_1, \text{day}_1) \\ H(\text{departure hour}_2, \text{day}_2) \\ \dots \\ H(\text{departure hour}_n, \text{day}_n) \end{bmatrix} = \begin{bmatrix} 1 & \text{departure hour}_1 & \text{day}_1 \\ 1 & \text{departure hour}_2 & \text{day}_2 \\ \dots & \dots & \dots \\ 1 & \text{departure hour}_n & \text{day}_n \end{bmatrix} \begin{bmatrix} w_0 \\ w_1 \\ w_2 \end{bmatrix}$$

Finding the optimal parameters

- To find the optimal parameter vector, \vec{w}^* , we can use the **design matrix** $X \in \mathbb{R}^{n \times 3}$ and **observation vector** $\vec{y} \in \mathbb{R}^n$:

$$X = \begin{bmatrix} 1 & \text{departure hour}_1 & \text{day}_1 \\ 1 & \text{departure hour}_2 & \text{day}_2 \\ \dots & \dots & \dots \\ 1 & \text{departure hour}_n & \text{day}_n \end{bmatrix} \quad \vec{y} = \begin{bmatrix} \text{commute time}_1 \\ \text{commute time}_2 \\ \vdots \\ \text{commute time}_n \end{bmatrix}$$

- Then, all we need to do is solve the **normal equations**:

$$X^T X \vec{w}^* = X^T \vec{y}$$

If $X^T X$ is invertible, we know the solution is:

$$\vec{w}^* = (X^T X)^{-1} X^T \vec{y}$$

Notation for multiple linear regression

- We will need to keep track of multiple features for every individual in our dataset.
 - In practice, we could have hundreds or thousands of features!
- As before, subscripts distinguish between individuals in our dataset. We have n individuals, also called **training examples**.
- Superscripts distinguish between **features**. We have d features.

departure hour: $x^{(1)}$

day of month: $x^{(2)}$

Think of $x^{(1)}$, $x^{(2)}$, ... as new variable names, like new letters.

Augmented feature vectors

- The augmented feature vector $\text{Aug}(\vec{x})$ is the vector obtained by adding a 1 to the front of feature vector \vec{x} :

$$\vec{x} = \begin{bmatrix} x^{(1)} \\ x^{(2)} \\ \vdots \\ x^{(d)} \end{bmatrix} \quad \text{Aug}(\vec{x}) = \begin{bmatrix} 1 \\ x^{(1)} \\ x^{(2)} \\ \vdots \\ x^{(d)} \end{bmatrix} \quad \vec{w} = \begin{bmatrix} w_0 \\ w_1 \\ w_2 \\ \vdots \\ w_d \end{bmatrix}$$

- Then, our hypothesis function is:

$$\begin{aligned} H(\vec{x}) &= w_0 + w_1 x^{(1)} + w_2 x^{(2)} + \dots + w_d x^{(d)} \\ &= \vec{w} \cdot \text{Aug}(\vec{x}) \end{aligned}$$

The general problem

- We have n data points, $(\vec{x}_1, y_1), (\vec{x}_2, y_2), \dots, (\vec{x}_n, y_n)$, where each \vec{x}_i is a feature vector of d features:

$$\vec{x}_i = \begin{bmatrix} x_i^{(1)} \\ x_i^{(2)} \\ \vdots \\ x_i^{(d)} \end{bmatrix}$$

- We want to find a good linear hypothesis function:

$$\begin{aligned} H(\vec{x}) &= w_0 + w_1 x^{(1)} + w_2 x^{(2)} + \dots + w_d x^{(d)} \\ &= \vec{w} \cdot \text{Aug}(\vec{x}) \end{aligned}$$

The general solution

- Define the **design matrix** $X \in \mathbb{R}^{n \times (d+1)}$ and **observation vector** $\vec{y} \in \mathbb{R}^n$:

$$X = \begin{bmatrix} 1 & x_1^{(1)} & x_1^{(2)} & \dots & x_1^{(d)} \\ 1 & x_2^{(1)} & x_2^{(2)} & \dots & x_2^{(d)} \\ \vdots & \vdots & \vdots & & \vdots \\ 1 & x_n^{(1)} & x_n^{(2)} & \dots & x_n^{(d)} \end{bmatrix} = \begin{bmatrix} \text{Aug}(\vec{x}_1)^T \\ \text{Aug}(\vec{x}_2)^T \\ \vdots \\ \text{Aug}(\vec{x}_n)^T \end{bmatrix} \quad \vec{y} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix}$$

- Then, solve the **normal equations** to find the optimal parameter vector, \vec{w}^* :

$$X^T X \vec{w}^* = X^T \vec{y}$$

Terminology for parameters

- With d features, \vec{w} has $d + 1$ entries.
- w_0 is the **bias**, also known as the **intercept**.
- w_1, w_2, \dots, w_d each give the **weight**, or **coefficient**, or **slope**, of a feature.

$$H(\vec{x}) = w_0 + w_1 x^{(1)} + w_2 x^{(2)} + \dots + w_d x^{(d)}$$

Interpreting parameters

Example: Predicting sales

- For each of 26 stores, we have:
 - net sales,
 - square feet,
 - inventory,
 - advertising expenditure,
 - district size, and
 - number of competing stores.
- **Goal:** Predict net sales given the other five features.
- To begin, we'll start trying to fit the hypothesis function to predict sales:

$$H(\text{square feet, competitors}) = w_0 + w_1 \cdot \text{square feet} + w_2 \cdot \text{competitors}$$

Question 🤔

Answer at q.dsc40a.com

$$H(\text{square feet}, \text{competitors}) = w_0 + w_1 \cdot \text{square feet} + w_2 \cdot \text{competitors}$$

What will be the signs of w_1^* and w_2^* ?

- A. $w_1^* +$ $w_2^* +$
- B. $w_1^* +$ $w_2^* -$
- A. $w_1^* -$ $w_2^* +$
- A. $w_1^* -$ $w_2^* -$

Let's find out! Follow along in [this notebook](#).

Question 🤔

Answer at q.dsc40a.com

Which feature is most "important"?

- A. square feet: $w_1^* = 16.202$
- B. competitors: $w_2^* = -5.311$
- C. inventory: $w_2^* = 0.175$
- D. advertising: $w_3^* = 11.526$
- E. district size: $w_4^* = 13.580$

Which features are most "important"?

- The most important feature is **not necessarily** the feature with largest magnitude weight.
- Features are measured in different units, i.e. different scales.
 - Suppose I fit one hypothesis function, H_1 , with sales in US dollars, and another hypothesis function, H_2 , with sales in Japanese yen (1 USD \approx 157 yen).
 - Sales is just as important in both hypothesis functions.
 - But the weight of sales in H_1 will be 157 times larger than the weight of sales in H_2 .
- **Solution:** If you care about the interpretability of the resulting weights, **standardize** each feature before performing regression, i.e. convert each feature to standard units.

Standard units

- Recall: to convert a feature x_1, x_2, \dots, x_n to standard units, we use the formula:

$$x_i \text{ (su)} = \frac{x_i - \bar{x}}{\sigma_x}$$

- Example: 1, 7, 7, 9.

- Mean: $\frac{1+7+7+9}{4} = \frac{24}{4} = 6$.

- Standard deviation:

$$\text{SD} = \sqrt{\frac{1}{4}((1-6)^2 + (7-6)^2 + (7-6)^2 + (9-6)^2)} = \sqrt{\frac{1}{4} \cdot 36} = 3$$

- Standardized data:

$$1 \mapsto \frac{1-6}{3} = \boxed{-\frac{5}{3}} \quad 7 \mapsto \frac{7-6}{3} = \boxed{\frac{1}{3}} \quad 7 \mapsto \boxed{\frac{1}{3}} \quad 9 \mapsto \frac{9-6}{3} = \boxed{1}$$

Standard units for multiple linear regression

- The result of standardizing each feature (separately!) is that the units of each feature are on the same scale.
 - There's no need to standardize the outcome (net sales), since it's not being compared to anything.
 - Also, we can't standardize the column of all 1s.
- Then, solve the normal equations. The resulting $w_0^*, w_1^*, \dots, w_d^*$ are called the **standardized regression coefficients**.
- Standardized regression coefficients can be directly compared to one another.
- Note that standardizing each feature **does not** change the MSE of the resulting hypothesis function!

Once again, let's try it out! Follow along in [this notebook](#).

Summary

- The normal equations can be used to solve multiple linear regression problems.
- Interpret the parameters as weights. Signs give meaningful information. Can only compare weight magnitude if data is standardized.
- On Friday: nonlinear features!
