Lecture 5

Simple Linear Regression

DSC 40A, Fall 2024

Agenda

- Simple linear regression.
- Minimizing mean squared error for the simple linear model.

Answer at q.dsc40a.com

Finding the best linear model

- Goal: Out of all linear functions $\mathbb{R} \to \mathbb{R}$, find the function H^* with the smallest mean squared error.
 - \circ Linear functions are of the form $H(x)=w_0+w_1x$.
 - \circ They are defined by a slope (w_1) and intercept (w_0) .
- ullet That is, H^* should be the linear function that minimizes

$$R_{ ext{sq}}(H) = rac{1}{n} \sum_{i=1}^n ig(y_i - H(x_i)ig)$$

We chose squared loss, since it's the easiest to minimize.

Minimizing mean squared error for the simple linear model

• Our goal is to find the linear hypothesis function $H^*(x)$ that minimizes empirical risk:

$$R_{ ext{sq}}(H) = rac{1}{n} \sum_{i=1}^n \left(y_i - H(x_i)
ight)^2$$

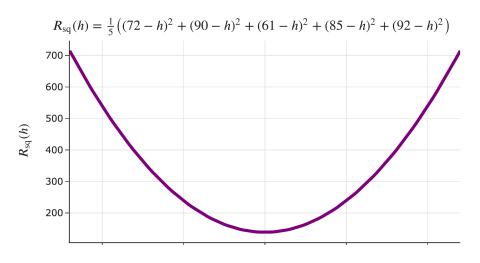

• Plugging in the linear hypothesis $H(x)=w_0+w_1x$, we can re-write $R_{
m sq}$ as a function of w_0 and w_1 :

$$\left| R_{ ext{sq}}(w_0, w_1) = rac{1}{n} \sum_{i=1}^n \left(y_i - (w_0 + w_1 x_i)
ight)^2
ight|$$

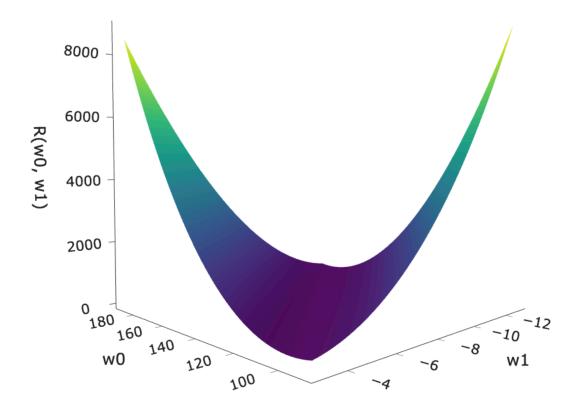

• How do we find the parameters w_0^* and w_1^* that minimize $R_{
m sq}(w_0,w_1)$?

Loss surface

For the constant model, the graph of $R_{\rm sq}(h)$ looked like a parabola.

What does the graph of $R_{\rm sq}(w_0,w_1)$ look like for the simple linear regression model?

Minimizing mean squared error for the simple linear model

Minimizing multivariate functions

• Our goal is to find the parameters w_0^* and w_1^* that minimize mean squared error:

$$R_{ ext{sq}}(w_0,w_1) = rac{1}{n} \sum_{i=1}^n \left(y_i - (w_0 + w_1 x_i)
ight)^2 .$$

- $R_{
 m sq}$ is a function of two variables: w_0 and w_1 .
- To minimize a function of multiple variables:
 - Take partial derivatives with respect to each variable.
 - Set all partial derivatives to 0.
 - Solve the resulting system of equations.
 - Ensure that you've found a minimum, rather than a maximum or saddle point (using the second derivative test for multivariate functions).

Example

Find the point (x, y, z) at which the following function is minimized.

$$f(x,y) = x^2 - 8x + y^2 + 6y - 7$$

Minimizing mean squared error

$$R_{ ext{sq}}(w_0,w_1) = rac{1}{n} \sum_{i=1}^n \left(y_i - \left(w_0 + w_1 x_i
ight)
ight)^2$$

To find the w_0^* and w_1^* that minimize $R_{\mathrm{sq}}(w_0,w_1)$, we'll:

- 1. Find $\frac{\partial R_{\text{sq}}}{\partial w_0}$ and set it equal to 0.
- 2. Find $\frac{\partial R_{\text{sq}}}{\partial w_1}$ and set it equal to 0.
- 3. Solve the resulting system of equations.

Question 🤔

Answer at q.dsc40a.com

$$R_{ ext{sq}}(w_0,w_1) = rac{1}{n} \sum_{i=1}^n \left(y_i - (w_0 + w_1 x_i)
ight)^2 .$$

Which of the following is equal to $\frac{\partial R_{\text{sq}}}{\partial w_0}$?

$$ullet$$
 A. $\dfrac{1}{n}\sum_{i=1}^n\left(y_i-(w_0+w_1x_i)
ight)$

• B.
$$-\frac{1}{n}\sum_{i=1}^n \left(y_i - (w_0 + w_1x_i)\right)$$

$$ullet$$
 C. $-rac{2}{n}\sum_{i=1}^n{(y_i-(w_0+w_1x_i))x_i}$

$$ullet$$
 D. $-rac{2}{n}\sum_{i=1}^n\left(y_i-(w_0+w_1x_i)
ight)$

$$egin{align} R_{ ext{sq}}(w_0,w_1) &= rac{1}{n} \sum_{i=1}^n \left(y_i - \left(w_0 + w_1 x_i
ight)
ight)^2 \ rac{\partial R_{ ext{sq}}}{\partial w_0} &=
onumber \ rac{\partial R_$$

$$egin{align} R_{ ext{sq}}(w_0,w_1) &= rac{1}{n} \sum_{i=1}^n \left(y_i - \left(w_0 + w_1 x_i
ight)
ight)^2 \ rac{\partial R_{ ext{sq}}}{\partial w_1} &= \ \end{array}$$

Strategy

We have a system of two equations and two unknowns (w_0 and w_1):

$$-rac{2}{n}\sum_{i=1}^n\left(y_i-(w_0+w_1x_i)
ight)=0 \qquad -rac{2}{n}\sum_{i=1}^n\left(y_i-(w_0+w_1x_i)
ight)\!x_i=0$$

To proceed, we'll:

- 1. Solve for w_0 in the first equation. The result becomes w_0^* , because it's the "best intercept."
- 2. Plug w_0^* into the second equation and solve for w_1 . The result becomes w_1^* , because it's the "best slope."

Solving for w_0^st

$$-rac{2}{n}\sum_{i=1}^n \left(y_i - (w_0 + w_1 x_i)
ight) = 0$$

Solving for w_1^*

$$-rac{2}{n}\sum_{i=1}^n{(y_i-(w_0+w_1x_i))x_i}=0$$

Least squares solutions

We've found that the values w_0^* and w_1^* that minimize $R_{
m sq}$ are:

$$w_1^* = rac{\displaystyle\sum_{i=1}^n (y_i - ar{y}) x_i}{\displaystyle\sum_{i=1}^n (x_i - ar{x}) x_i} \qquad \qquad w_0^* = ar{y} - w_1^* ar{x}$$

where:

$$ar{x} = rac{1}{n} \sum_{i=1}^n x_i \qquad \qquad ar{y} = rac{1}{n} \sum_{i=1}^n y_i$$

These formulas work, but let's re-write w_1^* to be a little more symmetric.

An equivalent formula for w_1^*

Claim:

$$w_1^* = rac{\displaystyle\sum_{i=1}^n (y_i - ar{y}) x_i}{\displaystyle\sum_{i=1}^n (x_i - ar{x}) (y_i - ar{y})} = rac{\displaystyle\sum_{i=1}^n (x_i - ar{x}) (y_i - ar{y})}{\displaystyle\sum_{i=1}^n (x_i - ar{x})^2}$$

Proof:

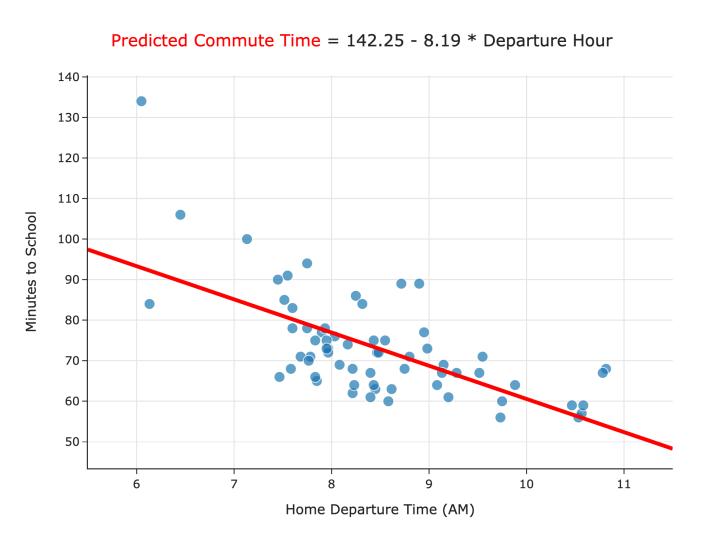

Least squares solutions

• The **least squares solutions** for the intercept w_0 and slope w_1 are:

$$w_1^* = rac{\displaystyle\sum_{i=1}^n (x_i - ar{x})(y_i - ar{y})}{\displaystyle\sum_{i=1}^n (x_i - ar{x})^2} \qquad \qquad w_0^* = ar{y} - w_1^* ar{x}$$

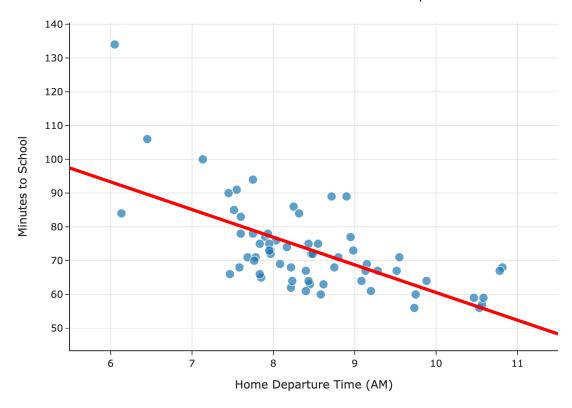

- We say w_0^* and w_1^* are **optimal parameters**, and the resulting line is called the regression line.
- The process of minimizing empirical risk to find optimal parameters is also called "fitting to the data."
- ullet To make predictions about the future, we use $H^*(x)=w_0^*+w_1^*x$.

Let's test these formulas out in code! Follow along here.

Causality

Can we conclude that leaving later causes you to get to school quicker?

What's next?

We now know how to find the optimal slope and intercept for linear hypothesis functions. Next, we'll:

- See how the formulas we just derived connect to the formulas for the slope and intercept of the regression line we saw in DSC 10.
 - They're the same, but we need to do a bit of work to prove that.
- Learn how to interpret the slope of the regression line.
- Discuss causality.
- Learn how to build regression models with multiple inputs.
 - To do this, we'll need linear algebra!
